DOA 1916 T, 20 heller part I, Coin production per die combination (2nd revision August 2018)
Untill the end of 2009 I collected all pictures of 20 Heller coins that I could find on internet. Some pictures were really to small or to bad to say anything but that they were 20 Heller 1916, so I had to throw them out. Together with the coins, in the lot I once bought, this resulted in 1077 coins for which, for almost all, the die combinations could be determined.
Then I stopped collecting each and every picture untill November 2013. As I had read somewhere that, if 5 coins are known for every die known, it may be assumed all dies are known, I kept only count of coins of die combinations of which I had not yet seen 5 coins.
Then Oktober 2013 I realised that, as I was determining the die combinations anyhow, I could, by keeping record of the amount of coins from each die combination, be able to calculate the amount of coins struck by each die combination. So I started collecting pictures again from all the coins appearing on internet.

To be really able to calculate the amount of coins struck by a die combination from the coins observed, the latter would have to be a random selection of the coins released from the mint. The circumstances at the time they were produced and the way they reached the market today make this improbable.
The coins were legal tender only for a few month. Coins from different die combinations may have been released at places a thousand kilometer apart in a country where walking was often the only way to get from one place to the other and that was almost instantly occupied and devided by two different colonial powers.
In Holland $77 \%$ of all coins were still Dutch one year after the introduction of the euro http://www.basvanleeuwen.net/Data.htm . By looking at the coins in your wallet today you can still tell in which euro-country you are.

This said there are some sparks of hope. A hundred years is a long time and some precautions can be taken.
First of all, larger lots of coins, which may have been gathered in a specific region of the country, could with some luck be recognized and be treated separately. My own lot may be considered as such and these coins have not been used in the calculations. A group of coins, which I call the Iringi lot, as it was gathered in that region, contained 27 HB2c-DB2e coins out of 91 in total. Then some dealers may be offering on internet only specific parts of much larger stocks they have accumulated. These coins have been not used in the calculations if they were recognized. When I started collecting pictures from internet, I could search back in time only for coins that figured in auctions. As a result auctionable coins like those HA with complete LL and the rarer copper types were vastly overrepresented. This was compensated by recalculating their figures based on their appearance between October 2013 and the end of 2014. The calculations per 2018 are based on 4160 coins,

Although the calculated figures may not represent the actual mintage figures, they are representative for the availability of coins from certain combinations on the market today, which for a collector may be just as important. The figures presented here are rounded to the nearest multiple of 500 . The complete data sheets can be found at
http://www.emuenzen.de/forum/threads/praegezahlen-deutsch-ost-afrika-doa-1916-ttabora.79225/
The +/- figures are the (rounded) statistical 95\% confidence interval. 95\% confidence interval means that the chance is less then $5 \%$, that you would have found as much items as you did, if the real total amount of items was more then this margin higher or lower then you calculated.

The larger the groups of die combinations, the smaller the chance that survival rates of single combinations have influence. For the main types actual mintage figures may be well within the confidence interval.
On the performance of the first die combinations (HB1-2-DB2) Schumacher remarked that only rarely they produced more then 10.000 coins. The calculated figures reflect this and show that later on the die quality was much improved.

Calculated mintage (2018) Amounts rounded to nearest multiple of $500, \quad+/$. $=95 \%$ confidence interval $99^{* *}$ die combinations, 25 HA-DA, 7 HA-DB, 7 HB-DA and 60** HB-DB
$152^{* *}$ dies, 26 HA dies, 24 DA dies, $54 \mathrm{HB}^{* *}$ dies and 48 DB dies $\quad{ }^{* *}$ HB2i and HB2i? counted as separate dies

The second table shows if and when a fifth coin was found for a die combination. March 2017 only 6 die combinations are still waiting for their fith coin.

Untill December 2009 I did know HA3a-DA4c only from paper.
Unknown before December 2009 were:
HA3k, a newly found die, used in combination with DA5b
HA3x, idem, used in combination with DB3b.
HB1s, idem, used in combination with DB2t
HB1f-DB2c, a newly found combination of previously known dies. 1 HB1f-DB2c had been in store as unidentified before December 2009.
HB2h-DB2p, a newly found combination of previously known dies. Uncertain how many may have escaped detection before the first one was recognized, 2 were found archived among questionmarked coins..
HA(C)1c-DA6a - coin alignment
HB3-4?-DB2? - coin alignment
HA2b-DB3u, a newly found combination of previously known dies.
Less then 5 coins per last revision
$5^{\text {th }}$ coin found after December 2009
*** included in HA3f-DA8c, HA3n only later found to be a seperate die.
**** as yet it could not be established whether or not HB2i and HB2i? are two different dies. From 2014 coins from these dies all of a sudden started to appear much more frequently.
